

Why CLR Connection Center?

The Business Case for West Capital Lending

April 2026

West Capital Lending

Internal Document · Prepared for Executives, Managers, and Team
Irvine, California · www.wlc.it.com

Executive Summary

CLR Connection Center is the internal operations platform built for West Capital Lending's Client Loan Representative team. It replaces a patchwork of spreadsheets, chat threads, and screenshots with a single application that runs the CLR workflow end-to-end — from the outbound call, through disposition and follow-up, to the signed end-of-day report that closes the book on the day.

The platform is live at www.wlc.it.com, installable as a PWA on iPhone, Android, and desktop, and is already the daily home screen for the team. It ingests Mojo dialer activity via webhook, pulls Bonzo prospects through the CRM's webhook, and serves 184 internal API endpoints behind role-based access control.

The three wins

- 1. Visibility.** Managers and admins see the whole team in real time — calls made, transfers, appointments, EOD submission status, and LO coverage — without asking anyone to paste numbers into a chat.
- 2. Consistency.** Every outcome is captured against a fixed taxonomy. Every EOD report looks the same, prints the same, and can be reviewed the same. There is one source of truth, not six.
- 3. Integration-ready.** The webhook ingestion layer for Mojo and Bonzo is already in production. Adding Encompass, Salesforce, Slack, or Google Calendar is a configuration exercise, not a rebuild.

Key Takeaway

CLR Connection Center turns the CLR role from a collection of personal systems into a repeatable, measurable, auditable workflow — without asking the team to change how they sell.

The Problem Before

Before CLR Connection Center, the CLR team operated on three disconnected surfaces. The dialer lived in Mojo. The CRM lived in Bonzo. The daily narrative — who called whom, what happened, which LOs were covered — lived in whatever tool a given CLR happened to favor that week. Nothing connected.

Scattered manual tracking

Call outcomes were logged in spreadsheets, sticky notes, and private message threads. Two CLRs working the same account could easily record the same conversation in three different places, or — worse — in no place at all. There was no enforced disposition vocabulary, so "callback" meant whatever the person typing it meant.

Missed follow-ups

Appointments and callbacks depended on someone remembering to set a reminder. When a CLR was out, their follow-ups went dark. When a borrower was promised a call-back next Tuesday, the promise lived in a notebook, not in a system that could surface it on Tuesday morning.

No single source of truth

Mojo knew call volume. Bonzo knew prospect status. Neither knew the full CLR picture, because the CLR workflow — the specific act of transferring a qualified borrower to a specific LO, capturing it as a direct transfer versus an appointment transfer, and noting which assigned LOs were actually worked — was not a first-class concept in either tool.

Inconsistent end-of-day reporting

EOD reports were submitted in whatever format the CLR chose that day: a Slack message, an email, a text, a screenshot. Rolling them up required a human to read every message and transcribe numbers. Week-over-week comparison was nearly impossible.

LO coverage blind spots

When an LO went on vacation, the message sometimes reached the CLR team and sometimes did not. Transfers got routed to an unavailable LO. Assignments were duplicated across CLRs. There was no system that held "who is working today" as authoritative data.

Key Takeaway

The pre-CCC workflow was not broken because the team was careless. It was broken because the team was asked to hold a multi-system process together with memory and goodwill. That only scales so far.

What the Platform Does Today

CLR Connection Center is organized around the actual daily rhythm of a CLR: open the app, see the assignment, run the script, log the outcome, handle follow-ups, close the day with an EOD report. Everything else — stats, chat, integrations, admin tooling — is built around that spine.

Outbound calling workflow

The **Script** page is the dialer companion. It opens next to Mojo and walks the CLR through the approved call flow, with the borrower's context visible at a glance from the **Directory** and **Assignments** pages. The **Dashboard** shows daily targets, KPIs, and a live activity-trend chart with a 1D / 1W / 1M / All Time toggle — so the CLR can see their own pace without leaving the app.

Outcome capture

Every call resolves into one of six outcomes: **transfer**, **appointment**, **fell through**, **callback requested**, **future contact**, or **no answer**. Transfers split into *direct transfer* and *appointment transfer*. Each outcome captures the borrower name, the assigned LO, a follow-up date, and free-text notes. This fixed taxonomy is what makes every downstream report possible.

Appointments and the 3-day badge

The **Appointments** page surfaces overdue, today, and upcoming follow-ups in separate lists. The sidebar badge counts only active appointment-type outcomes — appointment, callback requested, deferral, future contact — with a follow-up date in the next three days, and it excludes anything already converted to a transfer or already overdue. The number on the badge is the number the CLR actually has to act on.

EOD reporting with PDF export

The **EOD Report** is one submission per CLR per day, editable until submitted and read-only after. It captures calls made, transfers, appointments, notes, which assigned LOs were actually called, any additional LOs worked, and other notes. Past submitted reports export to a dedicated print-ready PDF — not a screenshot — with CLR identity, submission timestamp, outcome breakdown, transfer prospects, LO coverage rollup, activity log, and CLR plus Manager signature lines.

LO stats and LO Vacation

The **LO Stats** page shows per-loan-officer performance — how many transfers each LO is receiving, from whom, and at what conversion rate. **LO Vacation** lets admins mark LOs unavailable, and the daily assignment engine automatically skips them. Coverage is explicit, not assumed.

NMLS license tracking

A dedicated **NMLS** queue flags pending license checks with a sidebar badge, and a separate **NMLS License** reference page gives the team license-status context at a glance. Regulatory hygiene stops depending on anyone's memory.

Team chat and forum

Real-time **Chat** with an unread badge handles the quick "who's covering this?" conversation. The **Forum** handles long-form discussion — playbooks, post-mortems, FAQs — that would otherwise scroll away in a chat channel.

Daily assignment generation

From **Settings**, an admin generates one assignment per CLR per day. Once generated, the day is locked. An admin can unlock with a reason, and the unlock is written to the audit log. No CLR wakes up to a changed queue without a paper trail.

Mojo webhook ingestion

Mojo dialer sessions — call volume, contacts, DNC hits, transfers, appointments — flow into the platform through a configured webhook. A CSV import tool handles historical backfill, and a public-API sync stub is in place so the moment Mojo ships a public API, the switch-over is a configuration change. The **Mojo Sessions** page rolls up daily dialer activity per CLR.

Bonzo sync

Bonzo prospects sync in via webhook and appear in the **Bonzo Prospects** page. The **Contact Hub** unifies contacts across Mojo, Bonzo, and direct imports into one directory, so a CLR searching for a borrower does not need to guess which system they last lived in.

Admin, audit, and super-admin

Admins have their own reporting center, personal admin report, and settings for team goals, daily assignments, and integrations. Every sensitive action — assignment unlocks, user role changes, LO archive — writes to the **Audit Log**. Super admins can manage multiple organizations from one login, which keeps the platform ready for growth.

Key Takeaway

The platform already covers the full CLR day — not a slice of it. Every feature on this page is shipped, in production, and in use.

Measurable Impact

The value of CLR Connection Center is best understood as the things that can no longer go wrong. Each of the points below describes a specific failure mode that used to be routine and is now structurally prevented by the platform.

Every call disposition is captured

A call cannot be worked through the platform without a disposition. The six-outcome taxonomy is enforced in the UI, which means the team no longer has to reconcile three different names for the same event at the end of the week.

No duplicate data entry

Mojo activity and Bonzo prospects flow in automatically. A CLR does not retype what the dialer already knows, and an admin does not copy-paste prospect lists between tools.

Real-time team visibility

Managers see the **Stats** leaderboard, **LO Stats**, and individual activity trends as they happen. There is no lag between "what the team is doing" and "what the manager knows."

Consistent EOD closeouts

Every EOD report follows the same structure, prints to the same PDF layout, and includes CLR and Manager signature lines. Week-over-week review is now a matter of reading the same document multiple times — not a matter of interpretation.

Full audit trail for admin actions

Assignment unlocks, role changes, and LO archives are all logged. Anyone asking "who changed this and why?" has an answer in seconds.

Key Takeaway

The platform's impact is measured less in new numbers and more in the disappearance of old problems: missed follow-ups, duplicate entries, inconsistent reports, and untraceable changes.

The Future: Integrations

The single most important architectural choice in CLR Connection Center is that integrations are not bolt-ons. The webhook ingestion layer, the per-integration secret storage, and the unified Contact Hub were built from day one. Adding a new source or destination is an extension of an existing pattern.

Mojo public API

The Mojo integration is live today via webhook and CSV import, with a public-API sync stub already in place. When Mojo ships its public API, the platform is ready to pull richer data on a pull basis without waiting on a webhook event.

Deeper Bonzo sync

Bonzo syncs in today. A bidirectional extension — pushing CLR outcomes and transfer activity back into Bonzo as prospect notes or status updates — is the natural next step, and slots into the existing integration surface.

Encompass

Connecting to Encompass would give the CLR team visibility into loan-file status without logging into a second system. Transfers could be enriched with downstream pipeline context.

Salesforce

For any partner or affiliate flow that runs through Salesforce, the same webhook-plus-secret pattern already used for Mojo and Bonzo extends cleanly.

Slack and Google Calendar

Slack notifications for EOD submission, appointment reminders, and audit events; Google Calendar events for scheduled follow-ups and LO appointments — both are webhook-natural targets and can be rolled out incrementally per team request.

Key Takeaway

The integration roadmap is not speculative. The plumbing is already shipped; the next integrations are configuration work, not a new product.

Technical Foundation

Frontend	React 19 + Vite 7, TypeScript, Tailwind CSS, shadcn/ui, Wouter
Backend	Node.js + Express, TypeScript, 184 API endpoints under /api/*
Database	SQLite with prepared statements (better-sqlite3), /data/app.db on Railway volume
Auth	Session-based with secure cookies, role-based route guards, invite links
Hosting	Railway (Dockerfile builder), US East, bound to www.wlc.it.com
CI/CD	Push to main on GitHub → Railway auto-deploy via GitHub App
PWA	Installable on iPhone, Android, and desktop; service worker wclcc-v2
Health	GET /api/health returns { status, uptime, db } for monitoring

The stack is deliberately boring. It is the smallest set of well-understood components that can run the CLR workflow reliably and be extended by a single engineer without ceremony. The database file is 52 MB on a 500 MB volume, leaving ample headroom. Every push to **main** ships to production automatically.

Why This Matters

CLR Connection Center is the operational backbone of West Capital Lending's CLR team. It makes the work visible, makes the reporting consistent, and makes the next integration — whichever one the business picks next — an afternoon of configuration rather than a quarter of engineering. It is shipped, it is stable, and it is the platform the team will grow on.

The short version

One application. One source of truth. One clean surface to add the next integration onto. That is the business case.

Contact

Questions, feature requests, and access issues should go to the primary contact. The secondary contact handles escalations and manager-level coordination.
